

Relational Query Optimization

Chapter 15

1

Review

- **Implementation of single Relational Operations**
- **Choices depend on indexes, memory, stats,...**
- **Joins**
 - Block nested loops:
 - simple, exploits extra memory
 - Indexed nested loops:
 - best if 1 rel small and one indexed
 - Sort/Merge Join
 - good with small amount of memory, bad with duplicates
 - Hash Join
 - fast (enough memory), bad with skewed data

2

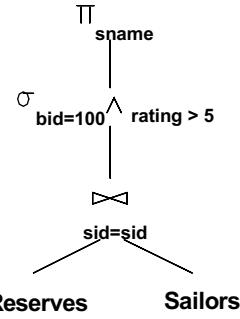

Query Optimization Overview

- Query can be converted to relational algebra
- Rel. Algebra converted to tree, joins as branches
- Each operator has implementation choices
- Operators can also be applied in different order!

```
SELECT S.sname  
FROM Reserves R, Sailors S  
WHERE R.sid=S.sid AND  
R.bid=100 AND S.rating>5
```

$\pi(sname)\sigma(bid=100 \wedge rating > 5)$ (Reserves \bowtie Sailors)

3

Query Optimization Overview (cont)

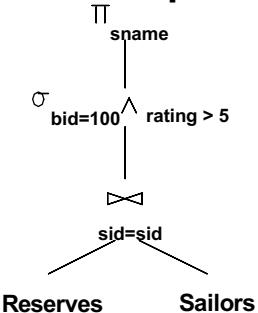

- **Plan:** Tree of R.A. ops (and some others) with choice of algorithm for each op.
 - Each operator typically implemented using a 'pull' interface: when an operator is 'pulled' for the next output tuples, it 'pulls' on its inputs and computes them.
- **Two main issues:**
 - For a given query, what plans are considered?
 - Algorithm to search plan space for cheapest (estimated) plan.
 - How is the cost of a plan estimated?
- **Ideally:** Want to find best plan.
- **Reality:** Avoid worst plans!

4

Recall: Iterator Interface

- A note on implementation:

Relational operators at nodes support uniform *iterator* interface:
 $Open()$, $get_next()$, $close()$

5

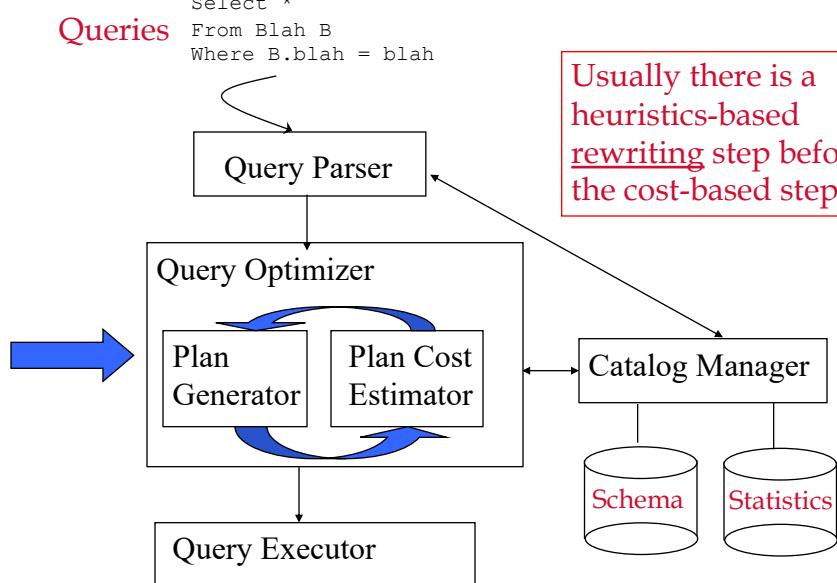

Cost-based Query Sub-System

Queries

```
Select *\nFrom Blah B\nWhere B.blah = blah
```

Usually there is a
heuristics-based
rewriting step before
the cost-based steps.

6

Schema for Examples

Sailors (*sid*: integer, *sname*: string, *rating*: integer, *age*: real)
 Reserves (*sid*: integer, *bid*: integer, *day*: dates, *rname*: string)

- **As seen in previous two lectures...**
- **Reserves:**
 - Each tuple is 40 bytes long, 100 tuples per page, 1000 pages.
 - Assume there are 100 boats
- **Sailors:**
 - Each tuple is 50 bytes long, 80 tuples per page, 500 pages.
 - Assume there are 10 different ratings
- **Assume we have 5 pages in our buffer pool!**

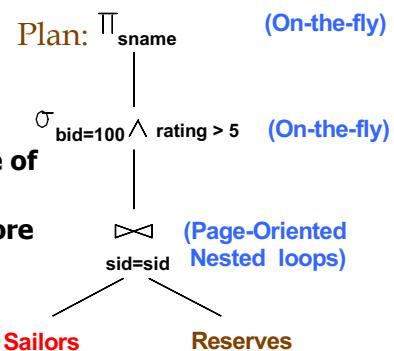

7

Motivating Example

```
SELECT S.sname
FROM Reserves R, Sailors S
WHERE R.sid=S.sid AND
      R.bid=100 AND S.rating>5
```

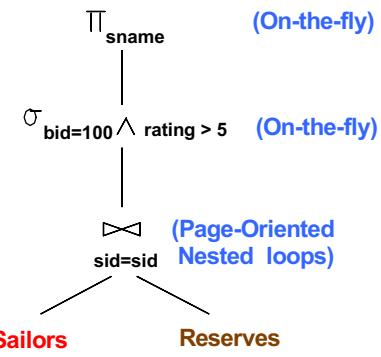

- **Cost: 500+500*1000 I/Os**
- **By no means the worst plan!**
- **Misses several opportunities: selections could have been 'pushed' earlier, no use is made of any available indexes, etc.**
- **Goal of optimization: To find more efficient plans that compute the same answer.**

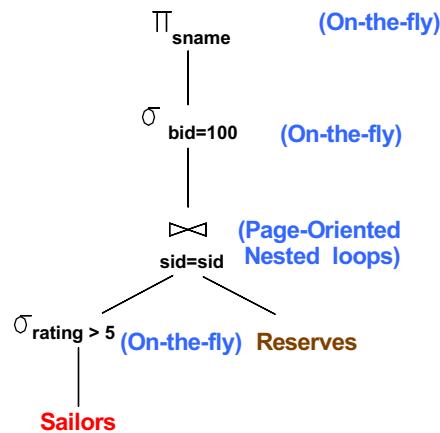

8

Alternative Plans – Push Selects (No Indexes)

500,500 IOs

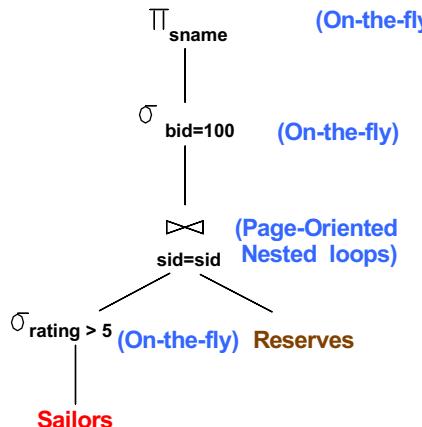

250,500 IOs

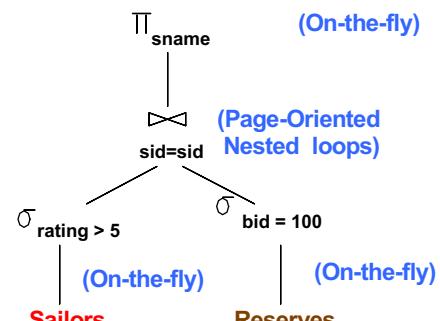

9

Alternative Plans – Push Selects (No Indexes)

250,500 IOs

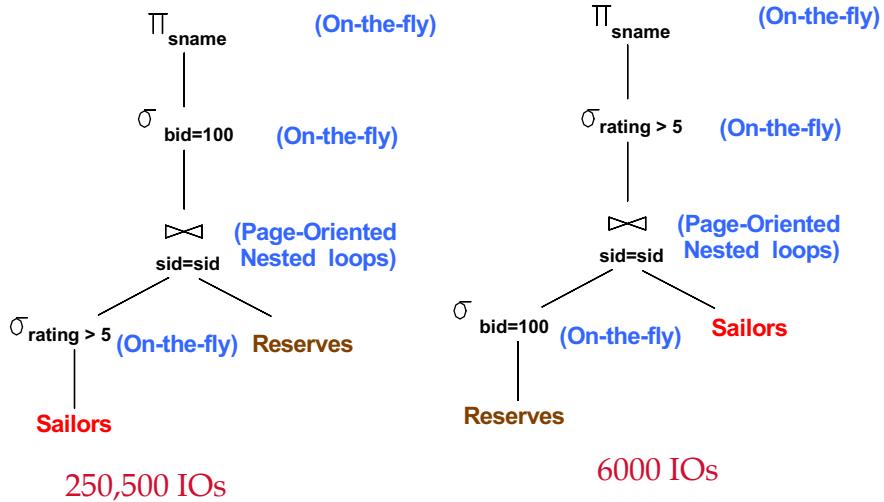

250,500 IOs

10

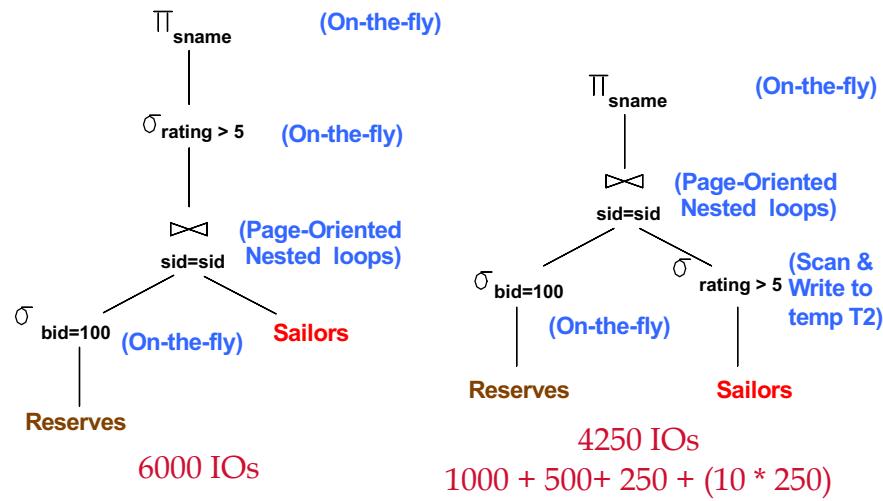

Alternative Plans – Push Selects (No Indexes)

11

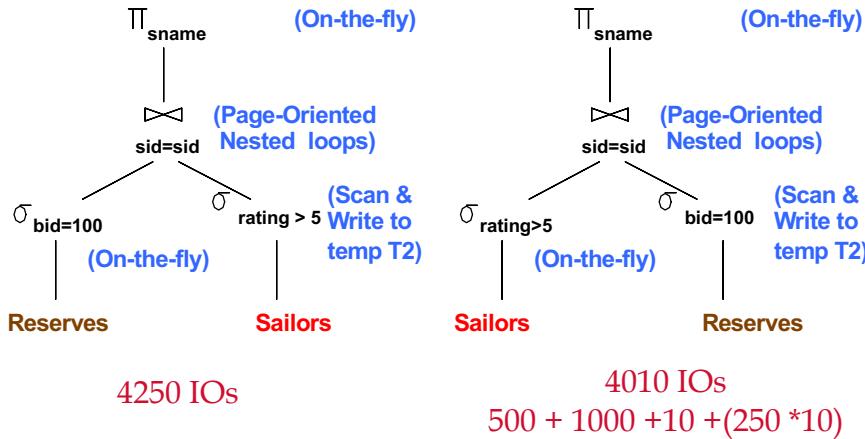

Alternative Plans – Push Selects (No Indexes)

12

Alternative Plans – Push Selects (No Indexes)

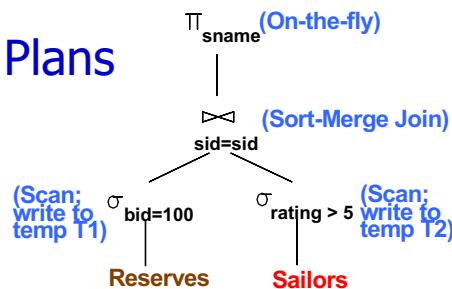

13

More Alternative Plans (No Indexes)

- Main difference:** **Sort Merge Join**
- With 5 buffers, cost of plan:**
 - Scan Reserves (1000) + write temp T1 (10 pages, if we have 100 boats, uniform distribution).
 - Scan Sailors (500) + write temp T2 (250 pages, if have 10 ratings).
 - Sort T1 ($2 * 2 * 10$), sort T2 ($2 * 3 * 250$), merge ($10 + 250$)
 - Total: 3560 page I/Os.
- If use BNL join, join = $10 + 4 * 250$, total cost = 2770.**
- Can also ‘push’ projections, but must be careful!**
 - T1 has only *sid*, T2 only *sid, sname*:
 - T1 fits in 3 pgs, cost of BNL under 250 pgs, total < 2000.

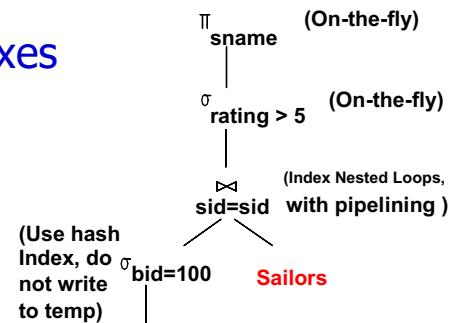

14

More Alt Plans: Indexes

- With clustered index on *bid* of Reserves, we get $100,000/100 = 1000$ tuples on $1000/100 = 10$ pages.
- INL with outer not materialized.**
 - Projecting out unnecessary fields from outer doesn't help.
 - Join column *sid* is a key for Sailors.
 - At most one matching tuple, unclustered index on *sid* OK.
 - Decision not to push *rating>5* before the join is based on availability of *sid* index on Sailors.
 - Cost:** Selection of Reserves tuples (10 I/Os); then, for each, must get matching Sailors tuple ($1000 * 1.2$); total 1210 I/Os.

15

What is needed for optimization?

- A closed set of operators**
 - Relational ops (table in, table out)
 - Encapsulation based on iterators
- Plan space, based on**
 - Based on relational equivalences
- Cost Estimation, based on**
 - Cost formulas
 - Size estimation, based on
 - Catalog information on base tables
 - Selectivity (Reduction Factor) estimation
- A search algorithm**
 - To sift through the plan space based on cost!

16

Summary

- **Query optimization is an important task in a relational DBMS.**
- **Must understand optimization in order to understand the performance impact of a given database design (relations, indexes) on a workload (set of queries).**
- **Two parts to optimizing a query:**
 - Consider a set of alternative plans.
 - Must prune search space; typically, left-deep plans only.
 - Must estimate cost of each plan that is considered.
 - Must estimate size of result and cost for each plan node.
 - *Key issues:* Statistics, indexes, operator implementations.

17

Query Optimization

- **Query can be dramatically improved by changing access methods, order of operators.**
- **Iterator interface**
- **Cost estimation**
 - Size estimation and reduction factors
- **Statistics and Catalogs**
- **Relational Algebra Equivalences**
- **Choosing alternate plans**
- **Multiple relation queries**
- **Will focus on “System R”-style optimizers**

18

Highlights of System R Optimizer

- **Impact:**
 - Most widely used currently; works well for < 10 joins.
- **Cost estimation:**
 - Very inexact, but works ok in practice.
 - Statistics, maintained in system catalogs, used to estimate cost of operations and result sizes.
 - Considers combination of CPU and I/O costs.
 - More sophisticated techniques known now.
- **Plan Space: Too large, must be pruned.**
 - Only the space of *left-deep plans* is considered.
 - Cartesian products avoided.

19

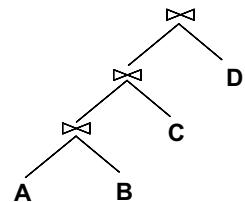

Query Blocks: Units of Optimization

- An SQL query is parsed into a collection of *query blocks*, and these are optimized one block at a time.
- Nested blocks are usually treated as calls to a subroutine, made once per outer tuple. (This is an over-simplification, but serves for now.)

```
SELECT S.sname
FROM Sailors S
WHERE S.age IN
    (SELECT MAX (S2.age)
     FROM Sailors S2
     GROUP BY S2.rating)
```

Outer block *Nested block*

- ❖ For each block, the plans considered are:
 - All available access methods, for each reln in FROM clause.
 - All *left-deep join trees* (i.e., right branch always a base table, consider all join orders and join methods.)

20

Schema for Examples

Sailors (sid: integer, sname: string, rating: integer, age: real)
Reserves (sid: integer, bid: integer, day: dates, rname: string)

- **Reserves:**

- Each tuple is 40 bytes long, 100 tuples per page, 1000 pages. 100 distinct bids.

- **Sailors:**

- Each tuple is 50 bytes long, 80 tuples per page, 500 pages. 10 ratings, 40,000 sids.

21

Translating SQL to Relational Algebra

```
SELECT S.sid, MIN (R.day)
FROM Sailors S, Reserves R, Boats B
WHERE S.sid = R.sid AND R.bid = B.bid AND B.color = "red"
AND S.rating = ( SELECT MAX (S2.rating) FROM Sailors S2)
GROUP BY S.sid
HAVING COUNT (*) >= 2
```

For each sailor with the highest rating (over all sailors), and at least two reservations for red boats, find the sailor id and the earliest date on which the sailor has a reservation for a red boat.

22

Translating SQL to Relational Algebra

```

SELECT S.sid, MIN (R.day)
FROM Sailors S, Reserves R, Boats B
WHERE S.sid = R.sid AND R.bid = B.bid AND B.color = "red"
AND S.rating = (SELECT MAX (S2.rating) FROM Sailors S2)
GROUP BY S.sid
HAVING COUNT (*) >= 2
    
```

Inner Block

$$\begin{aligned}
&\pi_{S.sid, \text{MIN}(R.day)} \\
&(\text{HAVING COUNT}(*)>2 \text{ (}} \\
&\text{GROUP BY } S.Sid \text{ (}} \\
&\sigma_{B.color = "red" \wedge S.rating = \text{val}} \text{ (}} \\
&\text{Sailors} \bowtie \text{Reserves} \bowtie \text{Boats})) \text{)})
\end{aligned}$$

23

Relational Algebra Equivalences

- **Allow us to choose different join orders and to 'push' selections and projections ahead of joins.**
- **Selections:** $\sigma_{c_1 \wedge \dots \wedge c_n}(R) \equiv \sigma_{c_1}(\dots \sigma_{c_n}(R))$ (Cascade)
- $\square \quad \sigma_{c_1}(\sigma_{c_2}(R)) \equiv \sigma_{c_2}(\sigma_{c_1}(R))$ (Commute)
- ❖ **Projections:** $\pi_{a_1}(R) \equiv \pi_{a_1}(\dots(\pi_{a_n}(R)))$ (Cascade)
- ❖ **Joins:** $R \text{ join } (S \text{ join } T) \equiv (R \text{ join } S) \text{ join } T$ (Associative)
 $(R \text{ join } S) \equiv (S \text{ join } R)$ (Commute)
- **This means we can do joins in any order.**

24

More Equivalences

- A projection commutes with a selection that only uses attributes retained by the projection.
- Selection between attributes of the two arguments of a cross-product converts cross-product to a join.
- A selection on just attributes of R commutes with $R \bowtie S$. (i.e., $\sigma(R \bowtie S) = \sigma(R) \bowtie S$)
- Similarly, if a projection follows a join $R \bowtie S$, we can ‘push’ it by retaining only attributes of R (and S) that are needed for the join or are kept by the projection.

25

Cost Estimation

- For each plan considered, must estimate cost:
 - Must estimate *cost* of each operation in plan tree.
 - Depends on input cardinalities.
 - We’ve already discussed how to estimate the cost of operations (sequential scan, index scan, joins, etc.)
 - Must estimate *size of result* for each operation in tree!
 - Use information about the input relations.
 - For selections and joins, assume independence of predicates.
 - In System R, cost is boiled down to a single number consisting of #I/O + *factor** #CPU instructions
 - Q: Is “cost” the same as estimated “run time”?

26

Statistics and Catalogs

- Need information about the relations and indexes involved. *Catalogs* typically contain at least:
 - # tuples (**NTuples**) and # pages (**NPages**) per rel'n.
 - # distinct key values (**NKeys**) for each index.
 - low/high key values (**Low/High**) for each index.
 - Index height (**IHeight**) for each tree index.
 - # index pages (**INPages**) for each index.
- Catalogs updated periodically.
 - Updating whenever data changes is too expensive; lots of approximation anyway, so slight inconsistency ok.
- More detailed information (e.g., histograms of the values in some field) are sometimes stored.

27

Size Estimation and Reduction Factors

SELECT attribute list

FROM relation list

WHERE term1 AND ... AND termk

- Consider a query block.
- Maximum # tuples in result is the product of the cardinalities of relations in the FROM clause.
- *Reduction factor (RF)* associated with each *term* reflects the impact of the *term* in reducing result size.
Result cardinality = Max # tuples * product of all RF's.
- *RF usually called "selectivity"*

28

Result Size Estimation

- *Result cardinality* =
Max # tuples * product of all RF's.
(Implicit assumption that values are uniformly distributed and terms are independent!)
 - Term $col=value$ (given index I on col)
RF = $1/NKeys(I)$
 - Term $col1=col2$ (**This is handy for joins too...**)
RF = $1/\text{MAX}(NKeys(I1), NKeys(I2))$
 - Term $col>value$
RF = $(High(I)-value)/(High(I)-Low(I))$
 - Note, if missing indexes, assume **1/10!!!**

29

Reduction Factors & Histograms

- For better estimation, use a histogram

No. of Values	2	3	3	1	8	2	1
Value	0..99	1..1.99	2..2.99	3..3.99	4..4.99	5..5.99	6..6.99

equiwidth

No. of Values	2	3	3	3	3	2	4
Value	0..99	1..1.99	2..2.99	3..4.05	4.06..4.67	4.68..4.99	5..6.99

equidepth

30

Think through estimation for joins

- **Does the above make sense for joins?**
- **Q: Given a join of R and S, what is the range of possible result sizes (in #of tuples)?**
 - If join is on a key for R (and a Foreign Key in S)?
 - A common case, can treat it specially
- **General case: join on {A} ({A} is key for neither)**
 - estimate each tuple r of R generates $NTuples(S)/NKeys(A,S)$ result tuples, so...
$$NTuples(R) * NTuples(S)/NKeys(A,\textcolor{red}{S})$$
 - but can also consider it starting with S, yielding:
$$NTuples(R) * NTuples(S)/NKeys(A,\textcolor{brown}{R})$$
 - If these two estimates differ, take the lower one!
 - Q: Why?

31

Enumeration of Alternative Plans

- **There are two main cases:**
 - Single-relation plans
 - Multiple-relation plans
- **For queries over a single relation, queries consist of a combination of selects, projects, and aggregate ops:**
 - Each available access path (file scan / index) is considered, and the one with the least estimated cost is chosen.
 - The different operations are essentially carried out together (e.g., if an index is used for a selection, projection is done for each retrieved tuple, and the resulting tuples are *pipelined* into the aggregate computation).

32

Cost Estimates for Single-Relation Plans

- **Index I on primary key matches selection:**
 - Cost is $\text{Height}(I)+1$ for a $B+$ tree.
- **Clustered index I matching one or more selects:**
 - $(N\text{Pages}(I)+N\text{Pages}(R)) * \text{product of RF's of matching selects.}$
- **Non-clustered index I matching one or more selects:**
 - $(N\text{Pages}(I)+N\text{Tuples}(R)) * \text{product of RF's of matching selects.}$
- **Sequential scan of file:**
 - $N\text{Pages}(R).$

☞ Recall: Must also charge for duplicate elimination if required

33

Example

```
SELECT S.sid  
FROM Sailors S  
WHERE S.rating=8
```

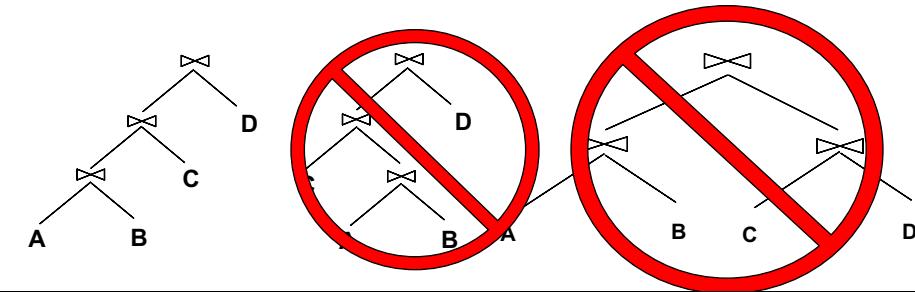

- **If we have an index on rating:**
 - Cardinality = $(1/\text{NKeys}(I)) * \text{NTuples}(R) = (1/10) * 40000$ tuples
 - Clustered index: $(1/\text{NKeys}(I)) * (N\text{Pages}(I)+N\text{Pages}(R)) = (1/10) * (50+500) = 55$ pages are retrieved. (This is the **cost**.)
 - Unclustered index: $(1/\text{NKeys}(I)) * (N\text{Pages}(I)+N\text{Tuples}(R)) = (1/10) * (50+40000) = 401$ pages are retrieved.
- **If we have an index on sid:**
 - Would have to retrieve all tuples/pages. With a clustered index, the cost is **50+500**, with unclustered index, **50+40000**.
- **Doing a file scan:**
 - We retrieve all file pages (**500**).

34

Queries Over Multiple Relations

- **Fundamental decision in System R:**
only left-deep join trees are considered.
 - As the number of joins increases, the number of alternative plans grows rapidly; *we need to restrict the search space.*
 - Left-deep trees allow us to generate all *fully pipelined* plans.
 - Intermediate results not written to temporary files.
 - Not all left-deep trees are fully pipelined (e.g., SM join).

35

Enumeration of Left-Deep Plans

- **Left-deep plans differ only in the order of relations, the access method for each relation, and the join method for each join.**
- **Enumerated using N passes (if N relations joined):**
 - Pass 1: Find best 1-relation plan for each relation.
 - Pass 2: Find best way to join result of each 1-relation plan (as outer) to another relation. (*All 2-relation plans.*)
 - Pass N: Find best way to join result of a (N-1)-relation plan (as outer) to the N' th relation. (*All N-relation plans.*)
- **For each subset of relations, retain only:**
 - Cheapest plan overall, plus
 - Cheapest plan for each *interesting order* of the tuples.

36

A Note on “Interesting Orders”

- An intermediate result has an “interesting order” if it is sorted by any of:
 - ORDER BY attributes
 - GROUP BY attributes
 - Join attributes of yet-to-be-planned joins

37

Enumeration of Plans (Contd.)

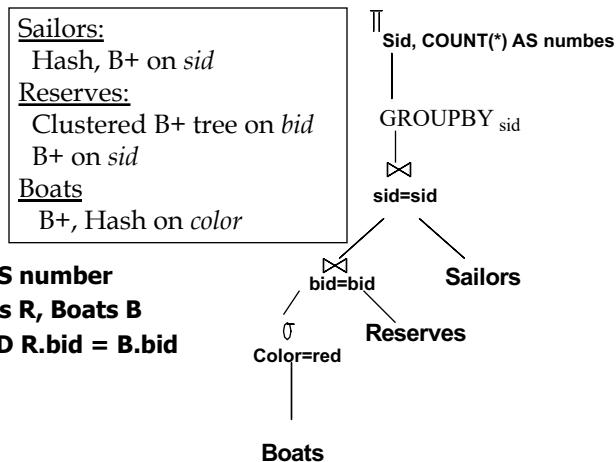

- An N-1 way plan is not combined with an additional relation unless there is a join condition between them, unless all predicates in WHERE have been used up.
 - i.e., avoid Cartesian products if possible.
- ORDER BY, GROUP BY, aggregates etc. handled as a final step, using either an ‘interestingly ordered’ plan or an additional sort/hash operator.
- In spite of pruning plan space, this approach is still exponential in the # of tables.
- Recall that in practice, COST considered is #IOs + factor * CPU Inst

38

Example

```
Select S.sid, COUNT(*) AS number
FROM Sailors S, Reserves R, Boats B
WHERE S.sid = R.sid AND R.bid = B.bid
      AND B.color = "red"
GROUP BY S.sid
```

- **Pass1: Best plan(s) for accessing each relation**
 - Reserves, Sailors: File Scan
 - Q: What about Clustered B+ on Reserves.bid???
 - Boats: B+ tree & Hash on color

39

Pass 1

- **Best plan for accessing each relation regarded as the first relation in an execution plan**
 - Reserves, Sailors: File Scan
 - Boats: B+ tree & Hash on color

40

Pass 2

- **For each of the plans in pass 1, generate plans joining another relation as the inner, using all join methods (and matching inner access methods)**
 - File Scan Reserves (outer) with Boats (inner)
 - File Scan Reserves (outer) with Sailors (inner)
 - File Scan Sailors (outer) with Boats (inner)
 - File Scan Sailors (outer) with Reserves (inner)
 - Boats hash on color with Sailors (inner)
 - Boats Btree on color with Sailors (inner)
 - Boats hash on color with Reserves (inner)
 - Boats Btree on color with Reserves (inner)
- **Retain cheapest plan for each pair of relations**

41

Pass 3 and beyond

- **For each of the plans retained from Pass 2, taken as the outer, generate plans for the next join**
 - eg Boats hash on color with Reserves (bid) (inner)
(sortmerge)
 inner Sailors (B-tree sid) sort-merge
- **Then, add the cost for doing the group by and aggregate:**
 - This is the cost to sort the result by sid, *unless it has already been sorted by a previous operator.*
- **Then, choose the cheapest plan**

42

Nested Queries

- Nested block is optimized independently, with the outer tuple considered as providing a selection condition.
- Outer block is optimized with the cost of 'calling' nested block computation taken into account.
- Implicit ordering of these blocks means that some good strategies are not considered. *The non-nested version of the query is typically optimized better.*

```
SELECT S.sname  
FROM Sailors S  
WHERE EXISTS  
(SELECT *  
FROM Reserves R  
WHERE R.bid=103  
AND R.sid=S.sid)
```

Nested block to optimize:

```
SELECT *  
FROM Reserves R  
WHERE R.bid=103  
AND R.sid= outer value
```

Equivalent non-nested query:

```
SELECT S.sname  
FROM Sailors S, Reserves R  
WHERE S.sid=R.sid  
AND R.bid=103
```

43

Points to Remember

- Must understand optimization in order to understand the performance impact of a given database design (relations, indexes) on a workload (set of queries).
- Two parts to optimizing a query:
 - Consider a set of alternative plans.
 - Good to prune search space; e.g., left-deep plans only, avoid Cartesian products.
 - Must estimate cost of each plan that is considered.
 - Output cardinality and cost for each plan node.
 - Key issues: Statistics, indexes, operator implementations.

44

Points to Remember

- **Single-relation queries:**
 - All access paths considered, cheapest is chosen.
 - *Issues:* Selections that *match* index, whether index key has all needed fields and/or provides tuples in a desired order.

45

More Points to Remember

- **Multiple-relation queries:**
 - All single-relation plans are first enumerated.
 - Selections/projections considered as early as possible.
 - Next, for each 1-relation plan, all ways of joining another relation (as inner) are considered.
 - Next, for each 2-relation plan that is `retained', all ways of joining another relation (as inner) are considered, etc.
 - At each level, for each subset of relations, only best plan for each interesting order of tuples is `retained' .

46

Summary

- Optimization is the reason for the lasting power of the relational system
- But it is primitive in some ways
- New areas: Rule-based optimizers, random statistical approaches (*e.g. simulated annealing*), adaptive runtime re-optimization (*e.g. eddies*)
